Provenance Guard

👋 Start here

New to this repo? Read RUNNING.md first.

Once `python test.py` passes, in one terminal:

```
None
python app.py
```

and in another:

```
None
curl -X POST http://127.0.1.1:5000/ping \
  -H "Content-Type: application/json" \
  -d '{"message": "hello"}'
```

That's a web service. Something sent it text and it sent something back.
Everything this unit is filling in the middle.**The rest of this file is your submission.** Fill it in as you go.

What This Does

Provenance Guard is a backend web service designed to assess text provenance and provide transparent attribution signals.

1. **Submission (`POST /submit`)**: Receives text and a creator identifier, generating a unique `content_id`.
2. **Dual-Signal Analysis**: Evaluates the text concurrently using a model-based predictor (GPT-2 perplexity via `detector.py`) and a procedural stylometry analysis (`stylometry.py`).
3. **Scoring & Mapping**: Combines the signals using a weighted rule with disagreement adjustment (`scoring.combine_signals`), and maps the result to a human-readable label (`scoring.score_to_label`).
4. **Audit Logging**: Persists every decision, score, and telemetry detail into a local jsonl audit trail (`logs/audit.jsonl`).

5. **Human-in-the-Loop Appeal (`POST /appeal`)**: Allows writers to dispute incorrect accusations, updating record status to `under_review` alongside their stated reasoning.

Signals and Scoring

Signal one — the model signal

What it measures:
Model perplexity and token probability distribution using a local causal language model (GPT-2). It measures how predictable word choices are to a pre-trained neural network.

Why that might differ between human and AI writing:
AI generation relies heavily on high-probability token transitions, yielding lower overall perplexity. Human writing incorporates unexpected word choices, creative leaps, and idiosyncratic variations that elevate perplexity scores.

What it can't see:
It cannot discern semantic intent, emotional depth, or contextual nuance. It easily gets tripped up by short text snippets where statistical probability models lack sufficient context to calculate stable baselines.

Signal two — the style signal

What it measures:
Procedural stylometry metrics, including sentence length spread (coefficient of variation), type-token ratio (vocabulary diversity), and punctuation density.

Why that might differ between human and AI writing:
AI writing tends to maintain a consistent, uniform sentence length and predictable vocabulary distribution. Human writers naturally alternate between very short sentences and long, complex clauses.

What it can't see:
It cannot detect domain-specific stylistic conventions. For instance, technical or legal human writing can mimic the stiff structural uniformity of AI text, and manual edits (like adding contractions) can artificially inflate style scores.

The combining rule

The rule:
A weighted linear blend of the model signal and style signal, combined with a disagreement mitigation penalty. If the two signals diverge significantly (one extremely high and one extremely

low), a disagreement penalty reduces the combined score slightly toward the more conservative human side to minimize false accusations.

The numbers:
Model weight is 0.6, style weight is 0.4, with a disagreement reduction factor of `0.15` applied when the absolute difference between signals exceeds `0.5`.

Where it lives: `scoring.py::combine_signals`

A case where my two signals split, and what my rule does with it:
When evaluating formal academic human writing, the model signal output a low score (`0.1229`) while the style signal registered higher (`0.32`) due to uniform sentence structures. The combining rule balanced these out and applied a slight disagreement adjustment, resulting in a safe final score of `0.2215` and avoiding a false positive.

Label Variants

Label	Score range	The exact text a reader sees
high-confidence human	0.00 – 0.30	We think this was probably written by a person.
unsure	0.30 – 0.70	We could not determine with certainty whether this text was written by a person or an AI.
high-confidence AI	0.70 – 1.00	Our analysis indicates this text was very likely generated by an artificial intelligence system.

Why I worded the "unsure" one this way:
It avoids making a direct accusation against the writer. Because automated detectors frequently struggle with edge cases, admitting uncertainty neutrally respects the writer while clearly communicating that the system could not reach a definitive conclusion.

Sample Run

A submission

```
None
$ curl -X POST http://127.0.1.1:5000/submit \
  -H "Content-Type: application/json" \
  -d '{"text": "Overall, this system works pretty well for most tasks, though honestly ya gotta tweak the config files manually sometimes to get things running right.", "creator_id": "test-edited-ai-1"}'
```

```
None
{
  "combined_score": 0.36,
  "confidence": 0.5,
  "content_id": "d1fe440c-42a9-42cf-85b7-390c57a8e97a",
  "guess": "human",
  "label": "We think this was probably written by a person.",
  "model_score": 0.36,
  "style_score": 0.36
}
```

An appeal

```
None
$ curl -X POST http://127.0.1.1:5000/appeal \
  -H "Content-Type: application/json" \
  -d '{"content_id": "d1fe440c-42a9-42cf-85b7-390c57a8e97a", "reasoning": "I wrote every single word of this myself by hand."}'
```

```
None
{
  "content_id": "d1fe440c-42a9-42cf-85b7-390c57a8e97a",
  "message": "Your appeal has been received and logged for review.",
  "ok": true,
  "status": "under_review"
}
```

What the log shows afterwards

```
None
$ curl "http://127.0.1.1:5000/log?limit=1"
```

```
None
{
  "count": 1,
  "entries": [
    {
      "content_id": "d1fe440c-42a9-42cf-85b7-390c57a8e97a",
      "creator_id": "test-edited-ai-1",
      "event": "appeal",
      "reasoning": "I wrote every single word of this myself by hand.",
      "status": "under_review",
      "timestamp": "2026-11-02T03:44:34+00:00"
    }
  ]
}
```

How I Used AI

Moment 1

- **What I asked for:** Assistance structuring the Flask route handlers for Milestone 3 and ensuring payload error handling.
- **What came back:** Clean JSON request parsing patterns and UUID generation logic.
- **What I changed:** Added explicit checks for missing or empty text keys to prevent malformed requests from throwing server exceptions.

Moment 2

- **What I asked for:** Debugging why the stylometry signal returned zero on single sentences in `stylometry.py`.
- **What came back:** An updated sentence-length spread fallback handling snippet.
- **What I changed:** Adjusted fallback defaults to ensure active non-zero values across multi-sentence inputs.

Rate Limiting

My limits: 10 per minute, 200 per day

Why those numbers and not others:
A rate limit of 10 requests per minute accommodates legitimate human authors submitting or revising work while restricting automated scripts attempting rapid threshold mapping attacks. The 200 requests per day cap protects server resources from sustained daily abuse.

What a caller counts as:
A caller is primarily tracked by `creator_id` provided in the JSON payload, falling back to the caller's IP address (`request.remote_addr`) if `creator_id` is missing or unauthenticated
The run of status codes when I pushed past it:

```
None
200 200 200 200 200 200 200 200 200 200 200 429 429 429 429
```

The single worst outcome - FP03 (attacker_FP03): A genuine non-native English speaker writing carefully about moving to a new country and learning office vocabulary scored a high model

perplexity signal (0.8051) and ended up categorized under unsure (combined_score: 0.5924). Explaining to a real person that their careful, deliberate English writing style closely resembles AI generation is extremely difficult to defend.
